ACM SIGSPATIAL GIS Cup - SHORTEST PATH

What is the shortest path problem ?

- ▶ The definition of the shortest path problem is to find a path between two nodes in a data set that minimizes the sum of the weights of the edges forming it.

The most important algorithms for solving this problem are;

Dijkstra's algorithm solves the single-source shortest path problem with non-negative edge weight.

Bellman-Ford algorithm solves the single-source problem if edge weights may be negative.

A* search algorithm solves for single-pair shortest path using heuristics to try to speed up the search.

Floyd-Warshall algorithm solves all pairs shortest paths.

Johnson's algorithm solves all pairs shortest paths and may be faster than Floyd-Warshall on sparse graphs.

Viterbi algorithm solves the shortest stochastic path problem with an additional probabilistic weight on each node.

```

mirror_mod = modifier_ob.
    # Add mirror object to mirror
    mirror_mod.mirror_object = mirror_ob
    # Mirror X operation
    operation == "MIRROR_X":
        mirror_mod.use_x = True
        mirror_mod.use_y = False
        mirror_mod.use_z = False
    # Mirror Y operation
    operation == "MIRROR_Y":
        mirror_mod.use_x = False
        mirror_mod.use_y = True
        mirror_mod.use_z = False
    # Mirror Z operation
    operation == "MIRROR_Z":
        mirror_mod.use_x = False
        mirror_mod.use_y = False
        mirror_mod.use_z = True

# Selection at the end -add
mirror_ob.select= 1
modifier_ob.select=1
context.scene.objects.active = mirror_ob
print("Selected" + str(modifier_ob.name))
mirror_ob.select = 0
bpy.context.selected_objects = [mirror_ob]
data.objects[one.name].select = 1
print("please select exactly one mirror")

--- OPERATOR CLASSES ---

class MirrorX(types.Operator):
    """Mirror X mirror to the selected object"""
    bl_label = "Mirror X"

    def execute(self, context):
        if context.active_object is not None:

```

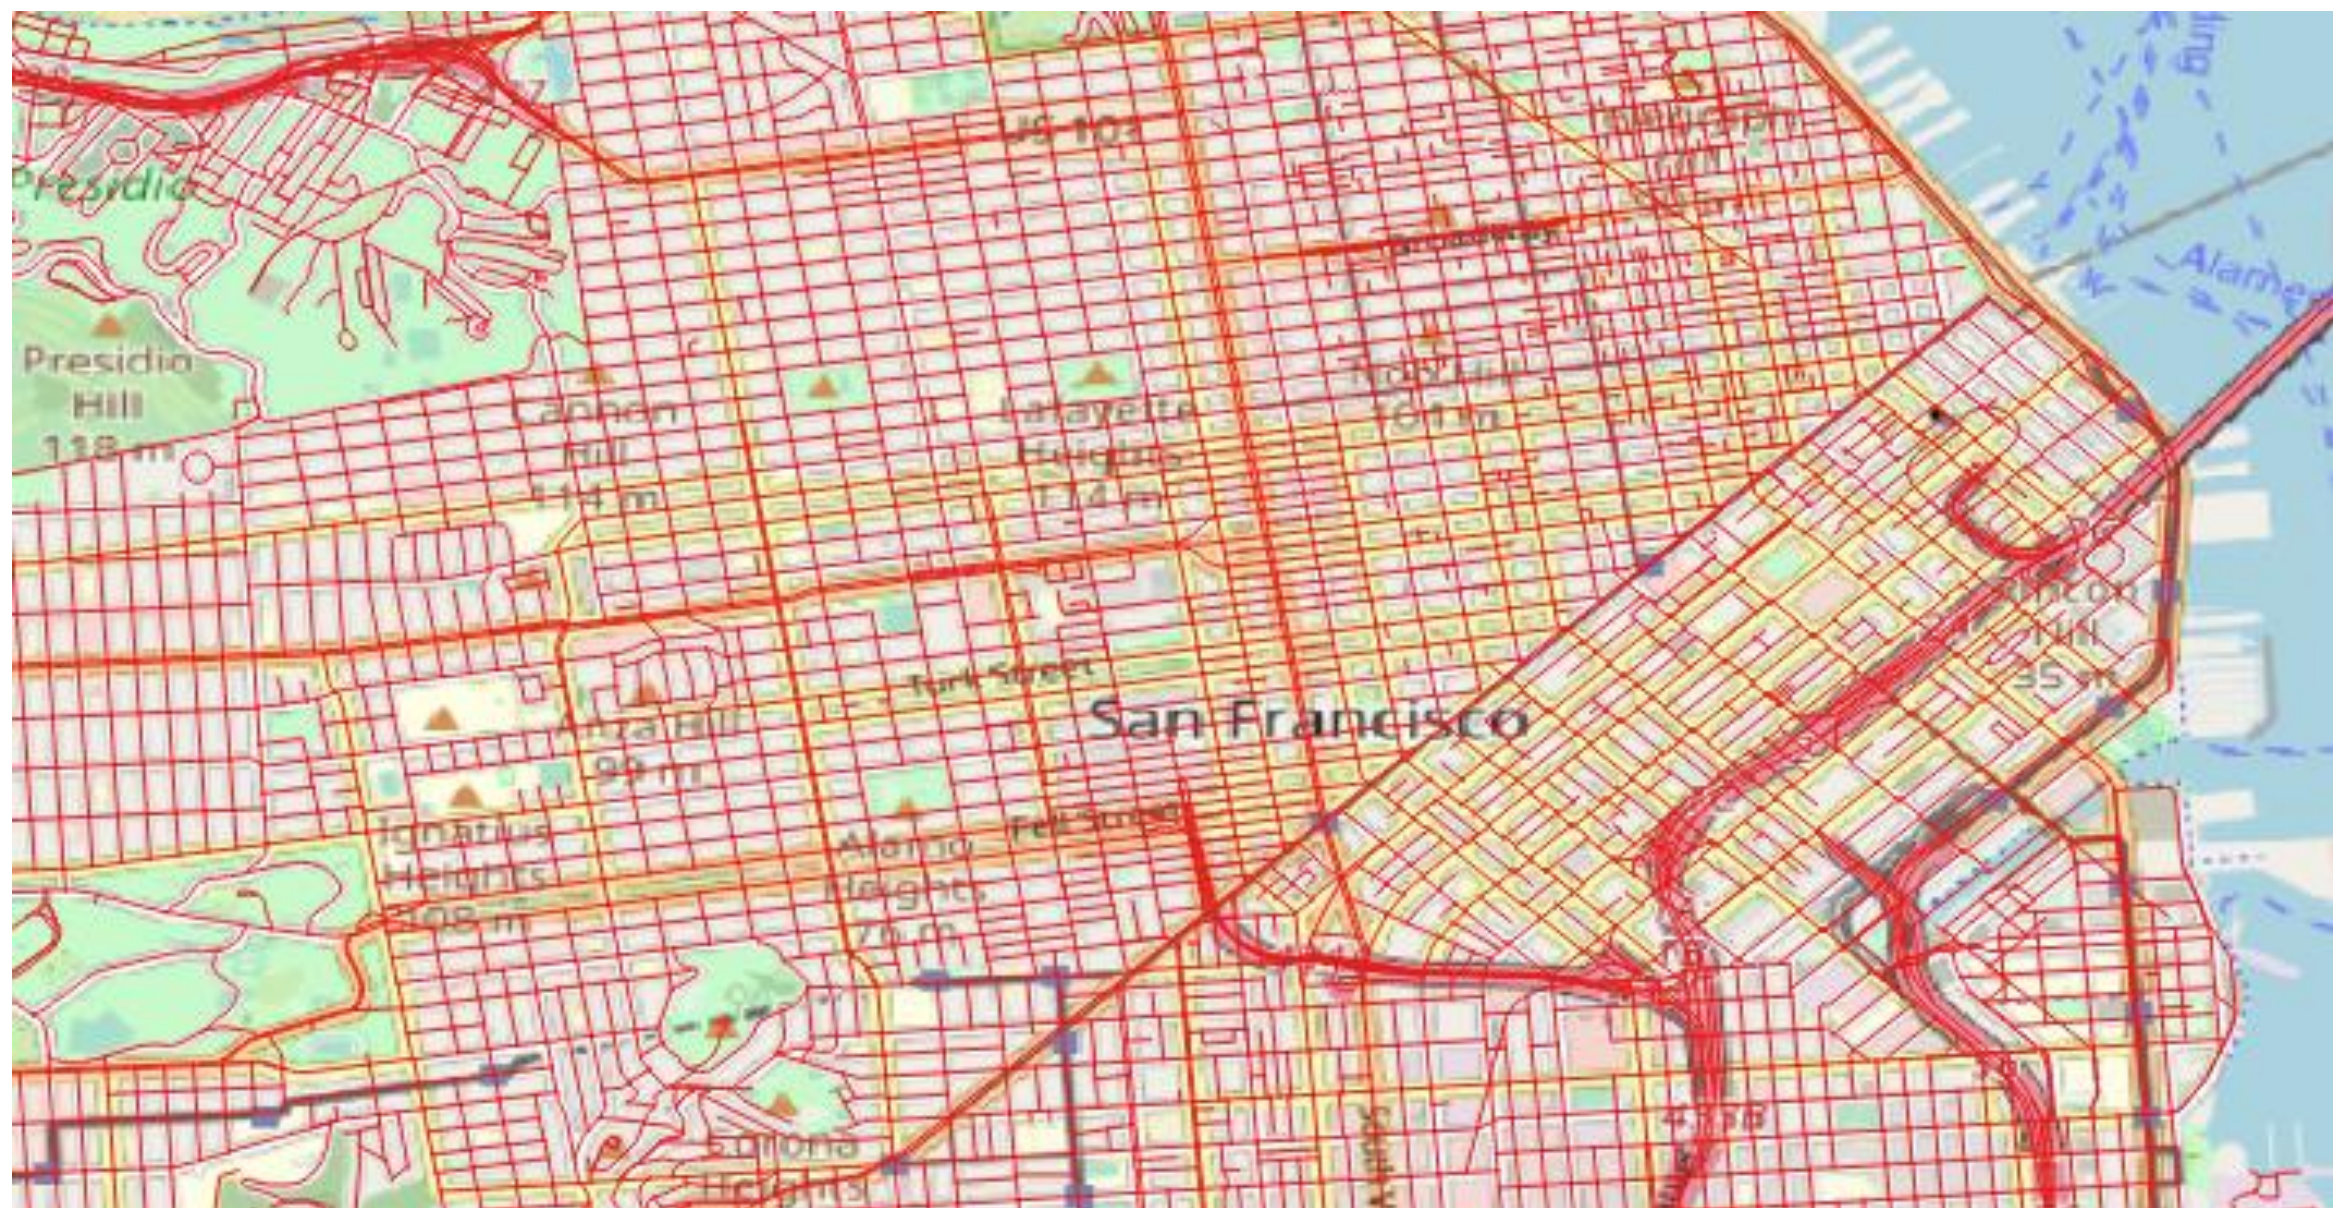

- Dijkstra's algorithm is an algorithm used to find the shortest path between nodes. Google Maps is used in OSPF (Open Shortest Path First) protocol, game programming, transportation networks. The main purpose of the algorithm is to calculate how to get from one node to another at the cheapest cost. We decided to build our project based on the Dijkstra's algorithm because it is more widely used among these algorithms and more suitable for our project when we researched it.

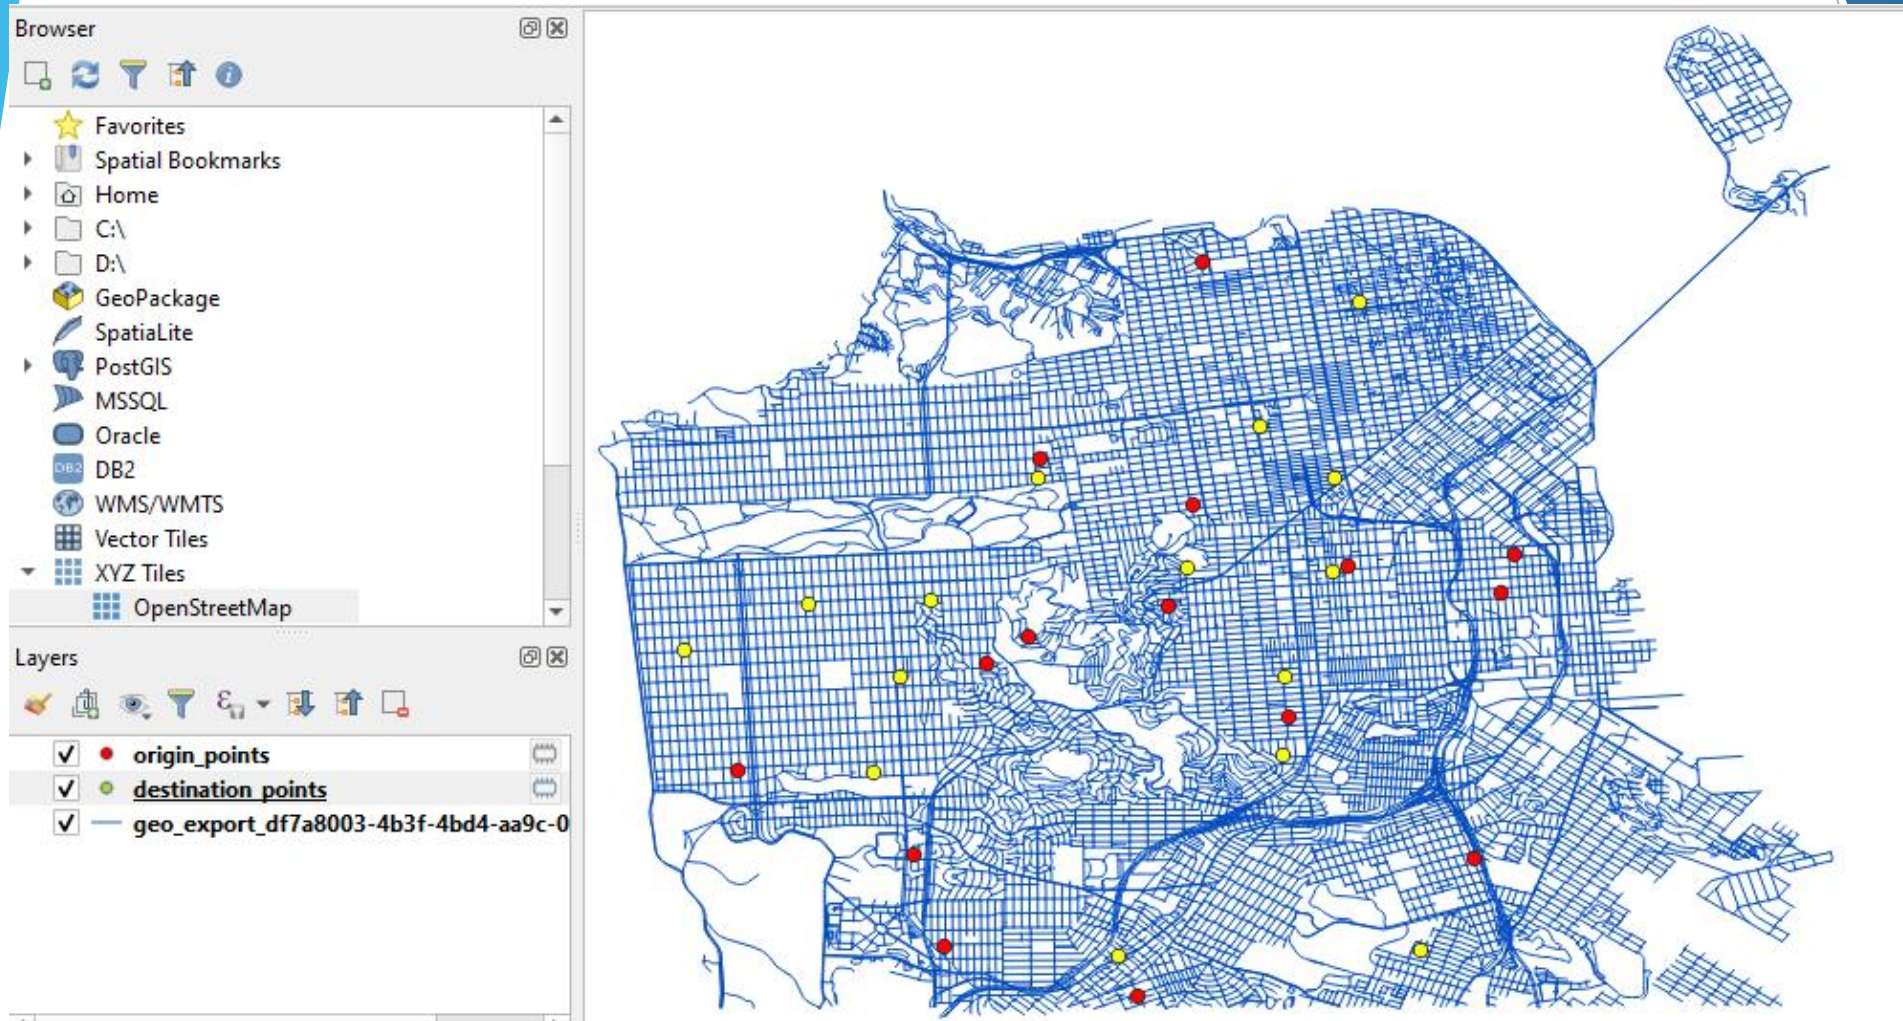

Finding and processing datasets

- ▶ When using San Francisco data, we used other road and node data from this city, as we need the attributes of the roads to be able to examine whether the roads are single lane or double lane.
- ▶ We traded between two points using road data and address data.
- ▶ We checked the accuracy of the road data on open street map and when we saw that it was correct, we decided to use this road data. Each side of the roads has an id, and the properties of the roads are included. In our code, the case of the road being one or two-way is also used.
- ▶ In the address file, we used the point cloud of San Francisco. This data file contains the latitude longitude value and id of each point.

First of all, we determined random 15 starting and 15 ending points from the address data in QGIS.

Shortest_Path_Matrix — Features Total: 225, Filtered: 225, Selected: 0

	origin_id	destination_id	entry_cost	network_cost	exit_cost	total_cost

16	403000	842000	25.0832649	1530.3972142	28.9729792	1584.4534583

Show All Features

- ▶ After creating the origin and destination points, we created the origin-destination matrices (OD Matrices) of these points. The total cost part in this picture gives the distance between two points.

- ▶ We wrote a command that separates the shortest distances between the points in the database manager.

The screenshot shows the DB Manager application window. On the left, the 'Providers' tree is expanded to 'Virtual Layers' > 'Project layers', where 'Shortest_Path_Matrix' is selected. The main panel has tabs for 'Info', 'Table', 'Preview', and 'Query (Project layers)'. The 'Query' tab is active, displaying a SQL query:

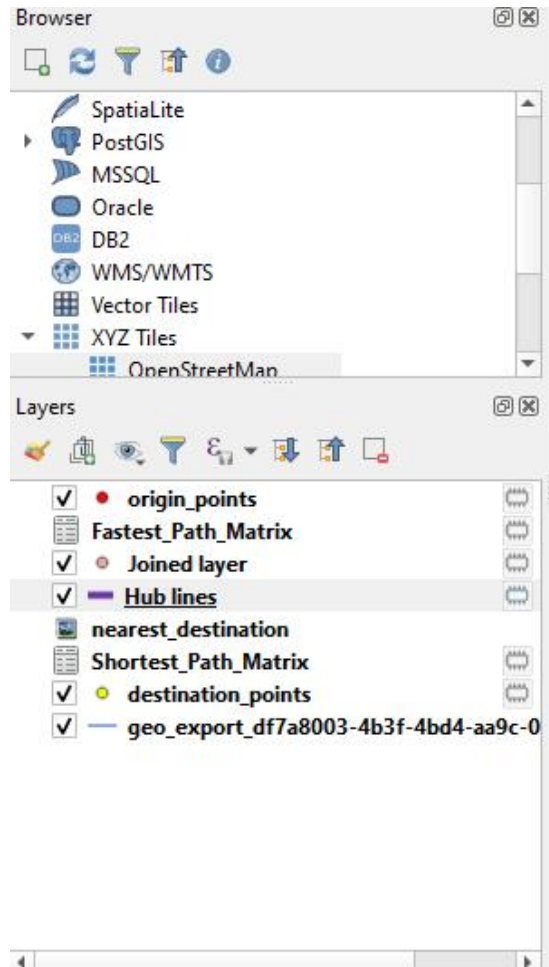

```
1 select origin_id, destination_id, min(total_cost) as shortest_distance
2 from 'Shortest_Path_Matrix' group by origin_id
```

Below the query editor, the 'Execute' button is pressed, showing '14 rows, 0.000 seconds'. The results are displayed in a table:

	origin_id	destination_id	shortest_distance
1	403000.0	842000.0	1584.453458261...
2	776000.0	798000.0	2192.35872235274
3	992000.0	12115000.0	2167.044694211...
4	3188000.0	12115000.0	1795.140165260...

At the bottom, the 'Load as new layer' section is checked. It includes options for 'Column with unique values' (set to 'origin_id'), 'Geometry column' (empty), 'Layer name (prefix)' (set to 'nearest_destination'), and 'Avoid selecting by feature id' (unchecked). Buttons for 'Retrieve columns', 'Set filter', 'Load', and 'Cancel' are present.

Create the Hub lines

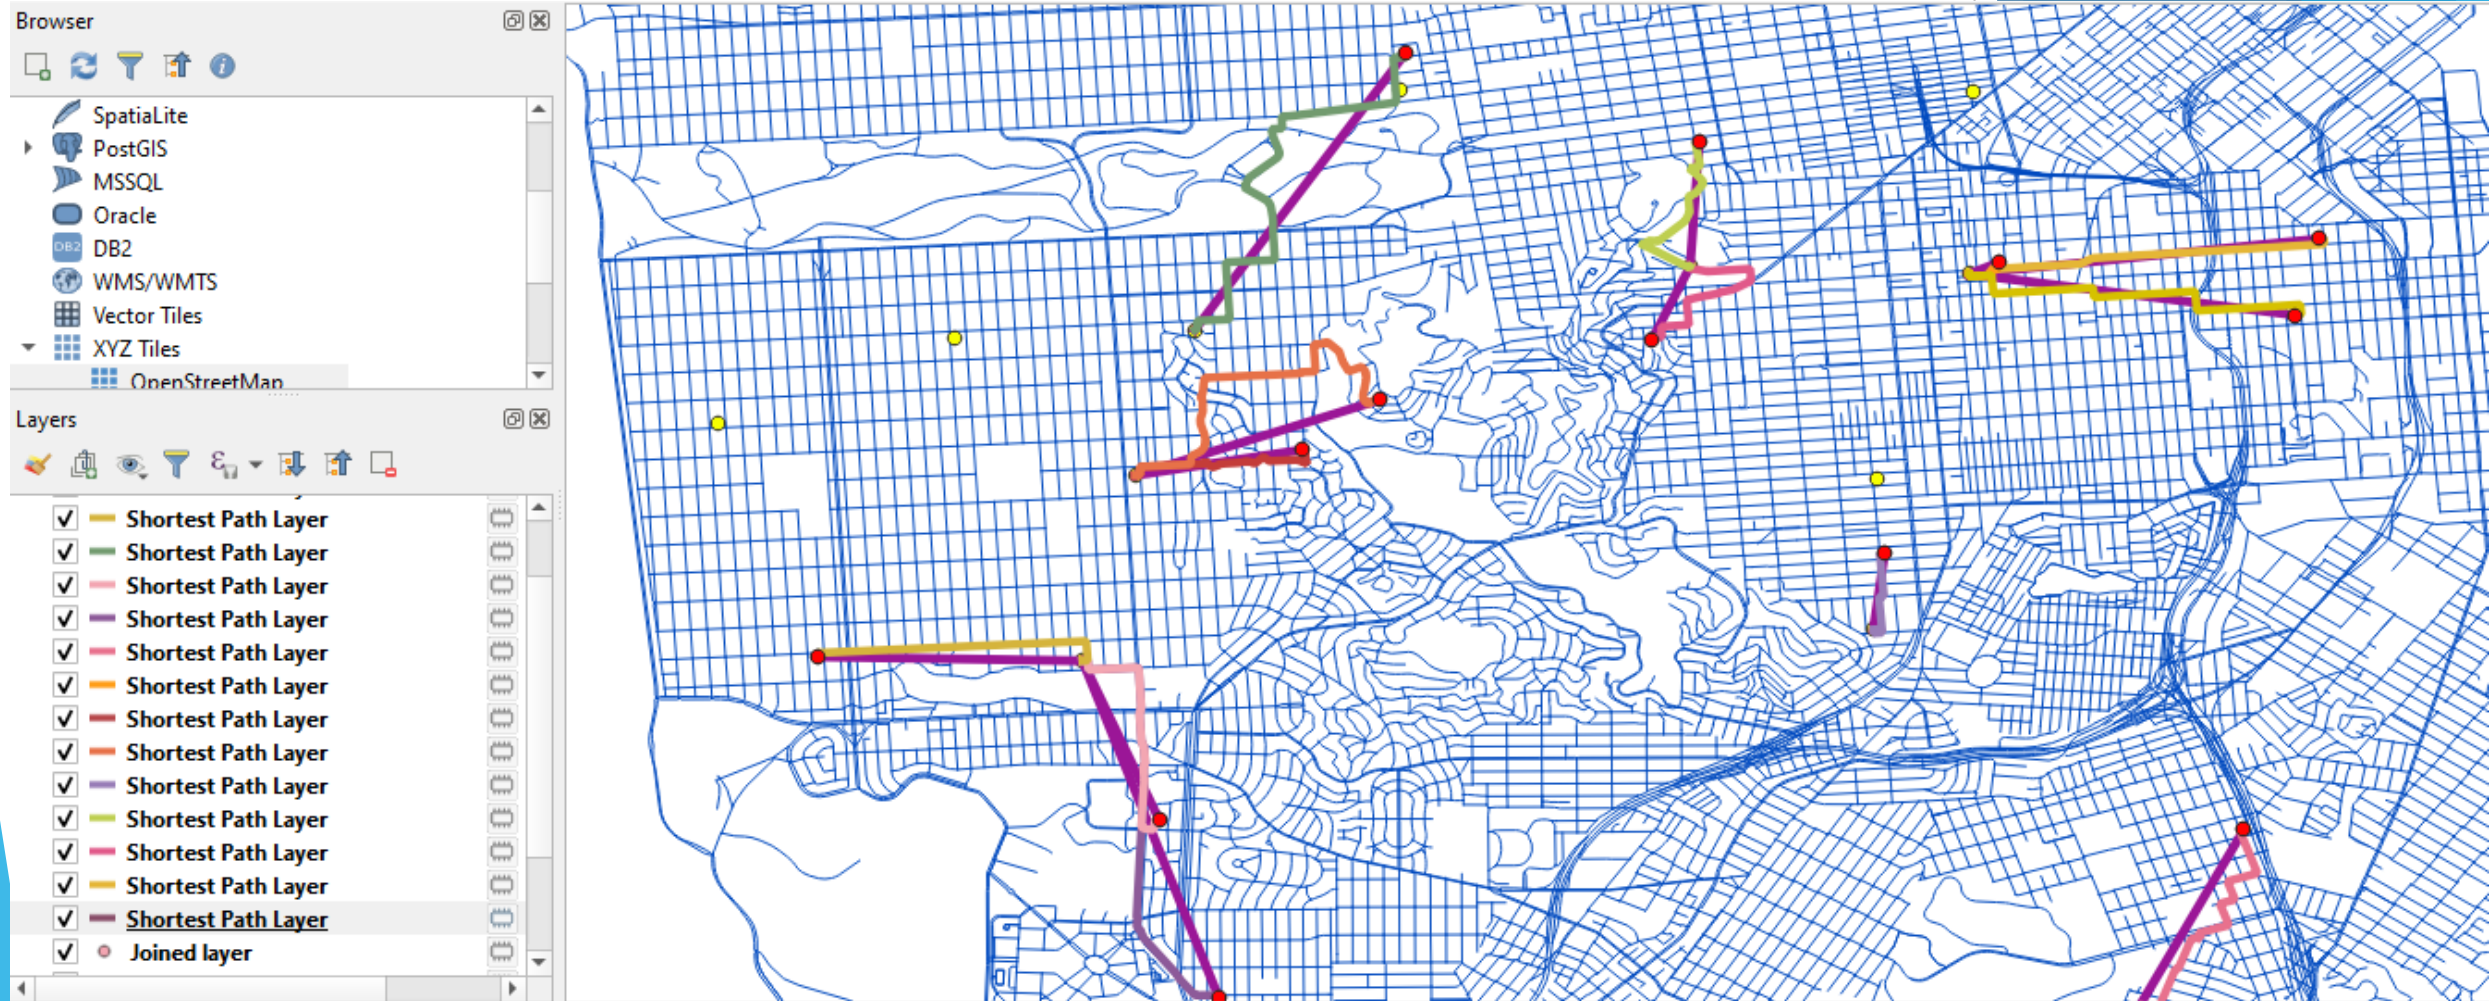

- We drew the hub line according to the distances we found in the shortest path matrix between the start and end points.

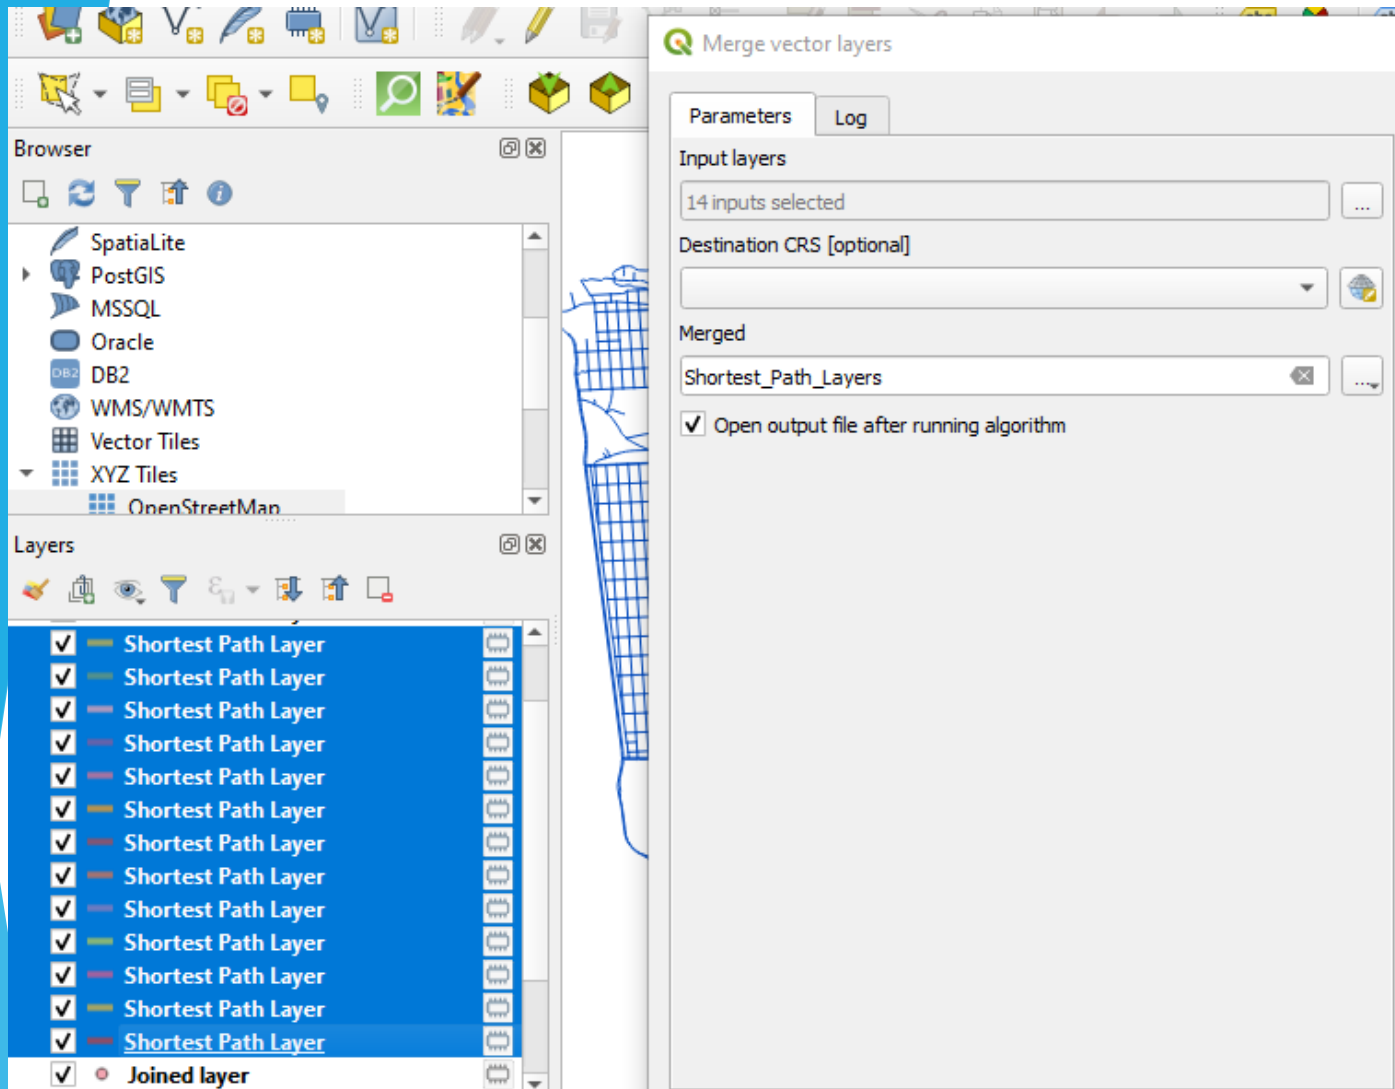

Using this code, we have plotted the shortest distances between points.

```
destination_layer = QgsProject.instance().mapLayersByName('destination_points')[0]
matrix = QgsProject.instance().mapLayersByName('nearest_destination')[0]

for f in matrix.getFeatures():
    origin_expr = QgsExpression('cnn={}'.format(f['origin_id']))
    destination_expr = QgsExpression('cnn={}'.format(f['destination_id']))
    origin_feature = origin_layer.getFeatures(QgsFeatureRequest(origin_expr))
    origin_coords = [(f.geometry().asPoint().x(), f.geometry().asPoint().y())
                     for f in origin_feature]
    destination_feature = destination_layer.getFeatures(QgsFeatureRequest(destination_expr))
    destination_coords = [(f.geometry().asPoint().x(), f.geometry().asPoint().y())
                          for f in destination_feature]
    params = {
        'INPUT': 'geo_export_df7a8003-4b3f-4bd4-aa9c-0bae12b615f9',
        'START_POINT': '{} {}'.format(origin_coords[0][0], origin_coords[0][1]),
        'END_POINT': '{} {}'.format(destination_coords[0][0], destination_coords[0][1]),
        'STRATEGY': 0,
        'ENTRY_COST_CALCULATION_METHOD': 0,
        'DIRECTION_FIELD': 'oneway',
        'VALUE_FORWARD': 'B\\n',
        'VALUE_BACKWARD': 'T\\n',
        'VALUE_BOTH': '',
        'DEFAULT_DIRECTION': 2,
        'SPEED_FIELD': None,
        'DEFAULT_SPEED': 5,
        'TOLERANCE': 0,
        'OUTPUT': 'memory:'
    }
    print('Executing analysis')
    processing.runAndLoadResults("gneat3:shortestpathpointtopoint", params)
```

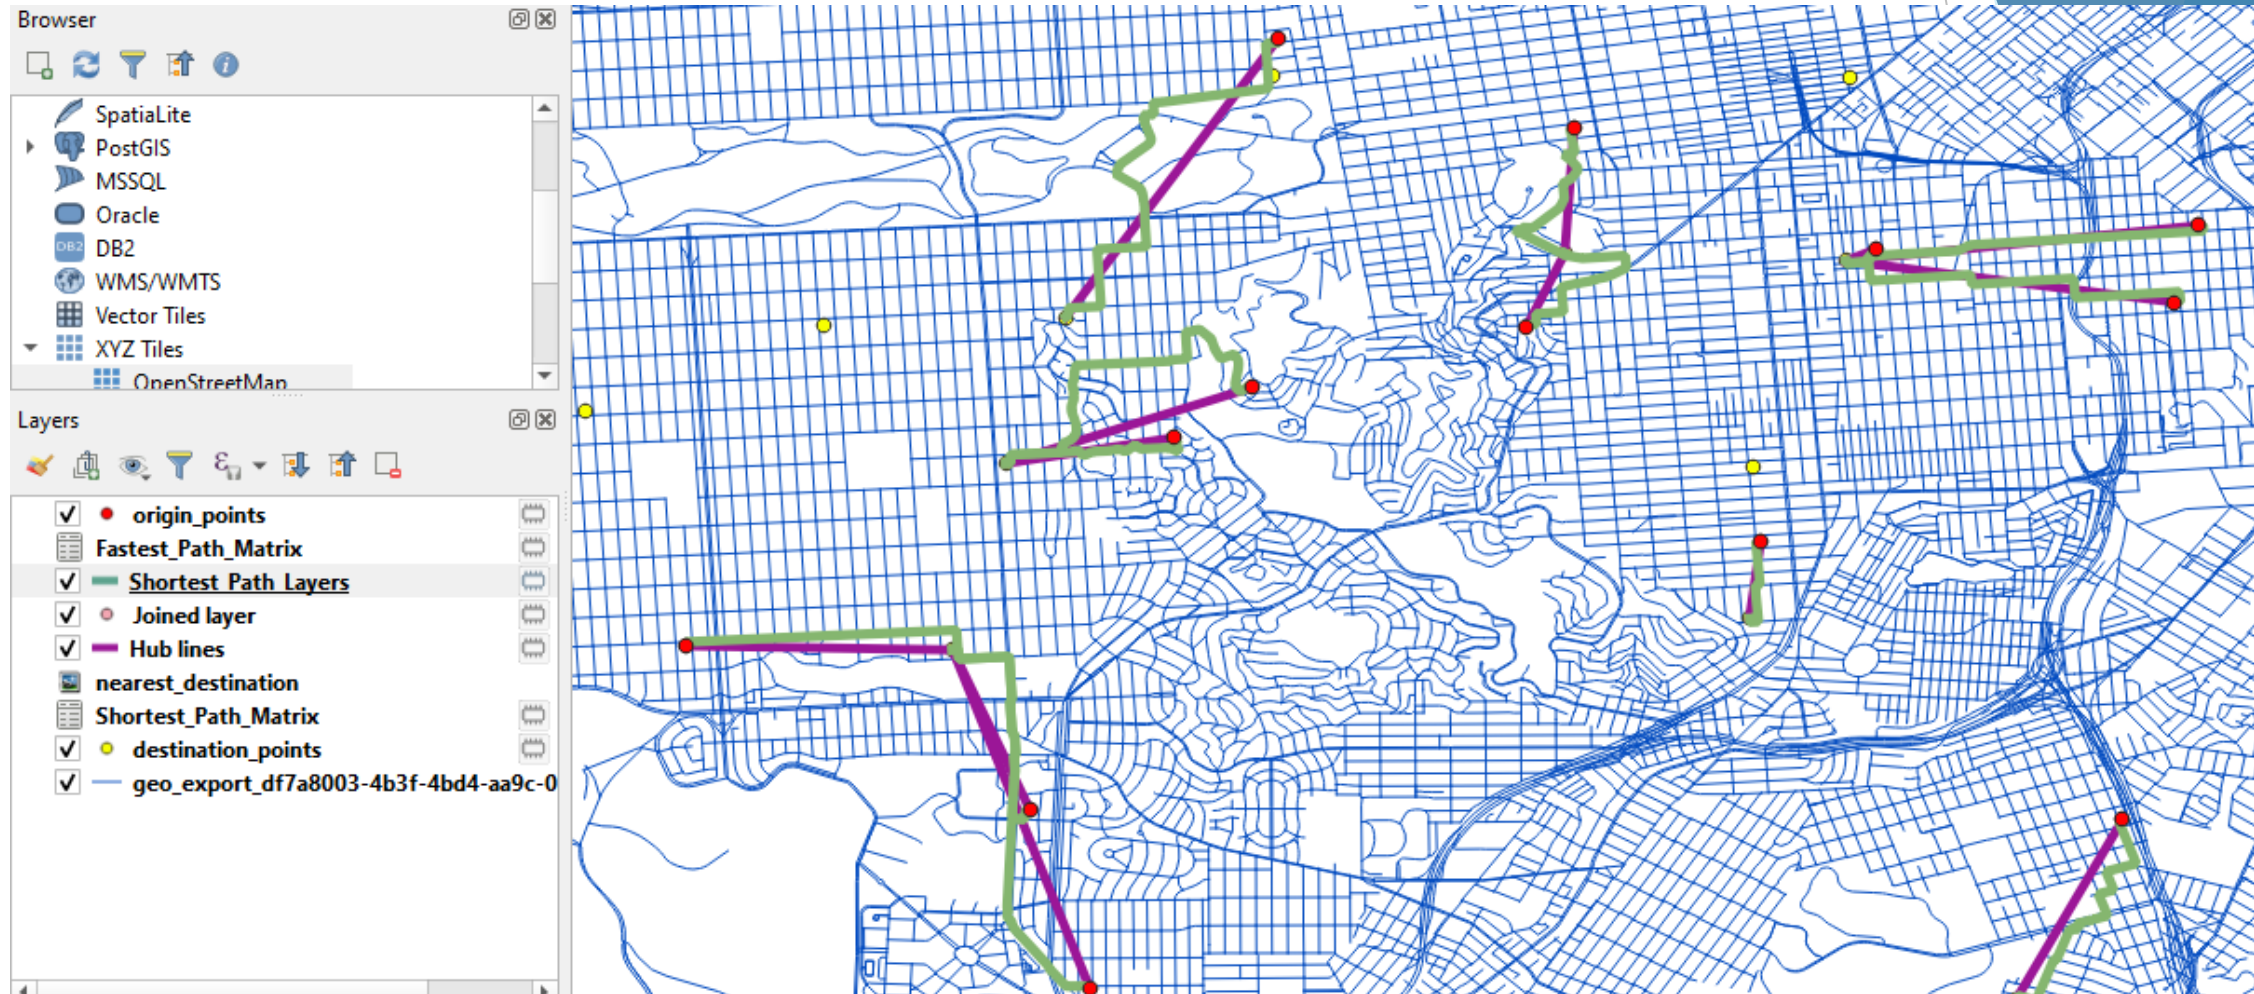

The outputs we get after the code

We combined these paths into a single layer.

Merged layer for shortest path

The background features a map with a blue grid overlay. A winding path is highlighted in green and purple, with several red and yellow dots marking specific locations. The map is partially obscured by a dark blue, semi-transparent overlay on the right side, which contains the text.
